## How does a automotive vacuum canister work

You have probably used them in the past, but have you ever stopped to think about how they work? While they may seem complicated, vacuum cleaners operate on a few straightforward principles, using a fairly simple set of main parts shared between all models. The following parts and principles are required for understanding how a vacuum cleaner works.Step 1 - Creating PressureA vacuum cleaner runs its motor using electricity from your outlet. It uses this motor to spin its fan rapidly. The fan has angled blades, which push air up towards the bag. This moves air from under the fan away, leaving an area of low air pressure below the fan, and near your floor. Air always moves from areas of high pressure to comparatively low pressure. This process is what will remove dirt from your floor.Because your fan has create an area of low pressure near your floor, air from your floor is going to move in to fill that space, due to how air pressure works. Sometimes, very small particles of dirt and dust will be lifted by the low pressure area as well. In addition to this, air takes larger, loose particles of dust and dirt with it using friction.Step 3 - The BrushMany vacuum cleaners, in addition to using a fan, also use a rotating brush that sweeps your floor. Sometimes, this rotating brush is powered by the very same motor that runs your vacuum cleaner's fan. Occasionally, this brush will be powered by being pushed back and forth across the floor instead. Either way, this brush serves the purpose of loosening trapped dirt and dust particles stuck in your carpet that would not have been picked up by the air pressure, and moving them to the surface, or even into the air, where they will be picked up easily.Step 4 - The BagOnce your vacuum cleaner has sucked in air and dirt particles, the high pressure area directly above your fan — remember, air travels from comparatively high to low pressure areas — causes them to continue to move upwards. At this point, the air and dirt particles enter your vacuum cleaner's porous bag. This bag is porous enough to allow air to pass through easily, but dense enough to trap dirt, dust, and any other larger particles that were on your floor. After exiting the bag, the air leaves the back of your vacuum cleaner, leaving any dirt that came with it trapped in the bag.Step 5 - Putting it TogetherRepeated applications of the rotating brush, when it is present, tend to loosen all dirt after a while, as well as trapping larger particles completely in the bristles and lifting them where they can be more easily sucked up into the vacuum cleaner's porous bag.With the simple principles described above, your floors are kept a little bit cleaner. During the early 20th century, horseless carriages started using glass to protect drivers from harsh winds. However, the standard form of glass used in those times didn't adequately protect occupants from flying debris. It also posed a risk to the occupants if an object struck the glass or if the vehicle was involved in an accident.In 1903, French chemist Edouard Benedictus stumbled upon the secret to shatter-resistant glass when he dropped a glass flask filled with a dried collodion film. He found that the glass coated with the film cracked, but kept its original shape. However, this laminated glass wouldn't be implemented in automobiles until the 1920s [source: Time].Automakers used laminated glass in their windshields to optimize occupant safety during accidents and to protect passengers from projectiles during normal driving conditions. For all its benefits, though, the first types of laminated glass offered limited puncture resistance. Today's laminated glass consists of a thin layer of polyvinyl butyral (PVB) inserted between two layers of solid glass.In addition to laminated glass, automakers began to use tempered glass in the late 1930s. This type of glass is used in the vehicle's side and back windows and gains its strength through a heating and rapid cooling process that strengthens the glass' outer surface as well as its core.By the 1960s, the American public had become increasingly aware that automobiles needed to be designed for more than just looks. This realization derived partly from consumer crusader Ralph Nader's work to expose the dangers posed by certain vehicles and the need for government safety standards. In response, the U.S. government formed the National Highway Traffic Safety Administration (NHTSA) in 1970 [source: Bowen].Since then, NHTSA has implemented regulations affecting all areas of vehicle safety, including automotive glass. Some of the Federal Motor Vehicle Safety Standards (FMVSS) for automotive glass include:FMVSS 205 -- This set clear standards for automotive window transparency and the strength of automotive glass required to keep occupants inside the vehicle during accidents.FMVSS 212 --This windshield mounting standard was established to ensure a certain level of windshield retention strength during accidents.FMVSS 216 -- This legislation implemented a standard for roof rigidity in case of a rollover.FMVSS 219 -- This standard states that no part of most passenger vehicles can penetrate the windshield more than 6 millimeters (0.24 inches) in a crash.Now that we know how automotive glass came to be, let's find out how it's made. how does vacuum canister work. what does a vacuum canister do on a car
